Introduction

The world of work, innovation, and society is changing as a result of artificial intelligence's (AI) quick development. Regarding how AI is predicted to change the nature of work in the future, the risks it may present and the path its development is taking, a number of important themes come to light during the interview. The discussion focuses on the ethical, financial, and social issues that come with AI advancements in addition to the amazing potential of these technologies to increase output and efficiency. With an emphasis on comprehending how AI may reshape professional environments, the risks it poses particularly with regard to job displacement and ethical issues and what we might expect in terms of AI's future trajectory, this report considers the key lessons learned from the film.

History and future of Artificial Intelligence

2.1: The future of work

The possibility for artificial intelligence (AI) to completely transform the nature of work itself is one of the main topics addressed in the conversation. Automation has traditionally been linked to the replacement of manual, repetitive, or routine tasks, like data entry or manufacturing. However, AI's trajectory for the future points to a much deeper integration into professional settings, where it will progressively assume more complex intellectual and decision-making tasks. Healthcare diagnosis, legal analysis, financial forecasting, and even aspects of creative production like writing and design are included in this.

In a nutshell the workforce of the future will likely be substantially smaller in some industries and have a very different composition in terms of job functions. Particularly in operational, clerical, and administrative roles, fewer humans might be needed to complete the same amount of work as AI advances. If proactive policies are not implemented to manage the transition, this decrease in the need for human labor could result in broad eviction. To make sure that workers are not left behind in the AI-driven economy, governments, academic institutions, and private organizations will need to work together.

In summary, artificial intelligence (AI) calls for a fundamental rethink of how we prepare for and perform at work, even as it offers enormous potential for innovation and productivity. As AI develops, it will overturn created norms of employment, redefine what a "career" is and emphasize flexibility, ongoing education and human-machine collaboration.

2.2: Great risks/threats posed by AI

The kind of digital intelligence we are making have become more superior to the kind of biological intelligence we have. These has created risks such as people misusing AI (most and short term) and AI getting smarter and making humans irrelevant. It is an existential threat that we have never have to deal with and how it is going to look like. According to **Yan Lar** we build this thing and we are always going to be in control. We build them to be obedient. According to **Elizer S.Yudkowski** this thing is going to wipe us out. If anybody is going to build it is going to wipe us all out. In **Prof Geoffrey Everest Hinton 's view** atomic bomb was very obvious that is dangerous but AI it is good for many things and we are not going to stop deployment.

Like the Europeans they have AI regulations but they are not designed to deal with most threats. They have a specific clause stating none of this regulations apply to military use of AI. Governments are ready to regulate companies and people but not themselves. What we really need is a kind of world government that works and run by intelligent thoughtful people and that's what we don't have instead we have capitalism.

One of the risks posed by AI is **cyber-attacks** such as fishing attacks. Fishing attacks are a type of cyber-attack where attackers attempt to trick individuals into revealing sensitive information such as usernames, passwords, credit card numbers or personal details by pretending to be a trustworthy entity. Some people think by 2030 AI can develop new cyber-attacks because they think for themselves and can draw new conclusions on their own.

Secondly we have **using AI to create nasty viruses**. The problem is that it just requires one crazy guy with a grudge, knows a little about molecular biology, knows a lot about AI and just wants to destroy the world.

Thirdly we have, corrupting **elections**. **Anybody** who wants to corrupt election can easily do that by getting information about everyone in the electorate. With is this in mind it is a bit worry ng because the person will have access to every personal details of anyone in the electorate.

Fourthly **algorithms are going to drive us into echo chambers**. This means creating two echo chambers like you tube and Facebook that will make people indignant that is feeling I am sort of angry but feeling righteous. It basically for profit gains which is show them whatever will make them click. At the end of it all people will have different shared reality according to what they click.

In addition, it leads to **creation of lethal autonomous weapons**. This means the weapons can kill you or even make a decision whether to kill you which is a great dream of the military industrial complex. Big countries will be able to invade small countries much easier and often because they don't have their soldiers being killed. Major risks include lack of accountability as it would be difficult to assign responsibility for their actions, malicious use and systems failures; leading to catastrophic consequences.

Lastly it would cause joblessness. For mundane intellectual labour AI is just going to replace everybody. One will have to be very skilled to have a job that AI cannot do. Both muscles and intelligence have been replaced only creativity is left but not for a long time.

2.3: Future trends in AI development

The interview shed light on a number of worth noting and rapidly developing developments that will influence artificial intelligence in the future. The use of generative AI systems that can produce original text, images, music and even code is one of the most notable. These tools, such as ChatGPT are quickly changing a variety of industries. Generative AI has enormous potential to boost productivity and creativity, but it also brings up fresh issues with false information, intellectual property and the veracity of human expression.

The movement toward human centric AI, which emphasizes matching AI systems with human values, ethical norms and emotional intelligence, is equally significant. These systems seek to promote and improve human well-being rather than merely mimic human intelligence. This entails creating AI that is more socially conscious, culturally sensitive and sympathetic. The foundation of human centric AI is the idea that people should benefit from technology not the technology coming to replace them.

Finally, the speaker underlined the significance of international cooperation in influencing AI's future. No one nation or organization can handle AI's problems on its own since its development and effects transcend national borders. People should pressure the government to force big companies to work on AI safety.

Conclusion

In conclusion, the interview highlights the significant and complex effects of AI on the nature of work and society in the future. AI has tremendous potential to boost productivity, resolve challenging issues and spur creativity, but it also carries serious risks that need to be properly addressed. These consist of moral conundrums, loss of employment and the possibility of abuse or unforeseen repercussions. It is imperative that careful regulation, inclusive discourse and a dedication to human-centered values serve as the foundation for AI's continued development. The choices we make today regarding the development, application and governance of AI will have a significant impact on its future in addition to the technology itself.
